Revised Estimates of Households and Average Household Size for Florida and Its Counties, 2010–2020

Stefan Rayer, Population Program Director
Conor Comfort, Research Demographer
Richard Doty, GIS Coordinator/Research Demographer
Suzanne Roulston-Doty, GIS Project Manager/Research Demographer

The Bureau of Economic and Business Research (BEBR) at the University of Florida produces population estimates for Florida and each of its cities and counties using the housing unit method. In this method, changes in population are based on changes in occupied housing units (or households), average household size, and the group quarters population. This is the most commonly used method for making local population estimates in the United States because it can utilize a wide variety of data sources, can be applied at any level of geography, and can produce estimates that are at least as accurate as those produced by any other method.

The two primary components of the housing unit method are the number of households and average household size (also called persons per households or PPH). BEBR has published estimates of the number of households and average household size annually since the late 1970s for Florida and its counties. These annual releases are postcensal estimates, i.e., they are based on results from the previous census that are updated using symptomatic indicators of changes in households and average household size available at the time. To correct for errors in the data used to construct the postcensal estimates, to draw on data that were not available when these estimates were produced, and to incorporate the results of the 2020 census, we have developed a revised series of state and county estimates for the number of households and average household size for 2011–2019. This new series follows an earlier set of revised estimates of households and average household size for Florida and its counties that covered the period 2001–2009 (BEBR, FPS Bulletin 179, December 2017).

This report includes the revised estimates of households and average household size for Florida and its counties from 2010–2020 and describes the methodology used to produce them. All estimates are as of April 1st of each year. We note that since these estimates have been created using a different methodology than in previous years, trends in the number of households and/or average household size may be different than those published previously.

Census definitions require persons to be counted as inhabitants of their usual place of residence, which is generally construed to mean the place where they live and sleep most of the time. A household is the person or group of people occupying a housing unit; by definition, the number of occupied housing units is the same as the number of households. Households refer solely to permanent residents, and a housing unit is still classified as vacant if all the occupants are temporary residents staying only for a few days, weeks, or months – even when it is continuously occupied. Because we follow these guidelines, temporary residents, such as tourists and snowbirds, are not included in the estimates shown here.

Data

Decennial census counts for 2010 and 2020 and the 2011–2019 BEBR intercensal population estimates (BEBR Special Population Report #11) formed the basis for developing these revised estimates of the number of households and average household size. They were produced as follows: first, we estimated the average household size for each county; then, we divided the population in households by the average household size. The population in households

equals the total population minus the population in group quarters. According to decennial census data, in 2010, there were 423,224 persons in group quarters in Florida, representing 2.25% of total population. In 2020, the group quarters population increased to 464,583, but its share of total population declined to 2.16%. There are many different types of group quarters, which can be institutional or non-institutional. In this analysis, we differentiate between inmates in federal and state correctional facilities and persons in all other types of group quarters. Counts for the former can change substantially from year-to-year, such as when facilities expand or contract, are closed, or new ones are built. We have a complete series of inmate counts in federal and state correctional facilities available for April 1 of all years from the Federal Bureau of Prisons and the Florida Department of Corrections. These were used to calculate the proportion of federal and state inmates out of the total population for each year between 2010 and 2020. For persons in other types of group quarters, we interpolated their proportions of total population between 2010 and 2020. Adding the proportions of federal and state inmates to the proportions of persons in all other types of group quarters gives us the overall proportion of the group quarters population out of total population for each year. Subtracting that proportion from total population provides estimates of the population in households.

To calculate average household size for 2011–2019, we used data from two main sources: the American Community Survey (ACS) and Internal Revenue Service (IRS). The ACS includes both 1-year and 5-year data. The 1-year data are timelier than the 5-year data, but they are only available for larger counties and can fluctuate substantially from year-to-year. Because of these limitations, we focused on the 5-year ACS data, which are collected over a 5-year period. We used the middle year of each 5-year period as a stand-in for the estimate year (e.g., 2009–2013 for 2011). While the 5-year ACS data provide PPH estimates that are more stable than those from the 1-year ACS, they still include a fair amount of noise, especially for smaller counties. In counties where the ACS data looked less reliable, we made certain adjustments, which are described in the Methodology section below.

To supplement the ACS data, we also used county income tax statistics from the IRS. Through tax year 2017, the IRS data included the number of exemptions per tax return, which can be used as a proxy indicator to calculate average household size. Starting in tax year 2018, IRS Form 1040 underwent a major redesign, and personal exemption deductions were suspended. However, since the filing status

and dependent filer information are still available, one can calculate PPH using the number of individuals per return, which is included in the more recent IRS data.

We note that while the ACS includes direct estimates of average household size, because of different residence rules and reference periods, the PPH values in the ACS do not always correspond closely to those in the decennial census. Therefore, similar to the IRS data, the ACS data are best used as a proxy for changes in average household size over periods of time. For that purpose, we scaled the PPH values provided by the ACS and IRS for 2010 and 2020 to the respective 2010 and 2020 census counts; PPH values for the intermediate years were scaled accordingly. The 2020 census only includes average household size at the national and state level; consequently, we had to derive PPH for counties by dividing the population not in group quarters by the number of occupied housing units.

Methodology

We created four data series, each controlled to the 2010 and 2020 census PPH values for their respective counties. The first series provided trends in PPH based on the 5-year ACS data (Model 1); the second series provided trends in PPH based on the IRS data (Model 2); and the third series was a linear interpolation between then 2010 and 2020 census PPH values (Model 3). The fourth series (Model 4) provided us with our final PPH estimates; it was a custom average of Models 1–3, with weights for each of the three series that varied by county.

For Model 4, we measured the fluctuation of the PPH estimates in the ACS and IRS data from year-to-year. Counties that showed greater fluctuations – as a proportion of the PPH change from the previous year – received lower weights for that respective series. That is, the data that appeared to be more reliable in a county were emphasized over the weaker data. Model 3, the data series based on an interpolation of the 2010 and 2020 census values, was weighted as a residual of the ACS and IRS weights. Therefore, in counties where the trend in PPH based on the ACS and/or IRS data appeared to be reliable, the interpolation weight was lower on average. Conversely, in counties where the trend in PPH based on the ACS and/or IRS data appeared less reliable, the interpolation weight was comparatively higher.

Overall, the IRS data exhibited less fluctuation and noise than the ACS data. Accordingly, we initially set slightly lower county target weights for the ACS data (10% to 35%)

compared to the IRS data (15% to 40%); the residual weights for the linear interpolation varied between 25% and 75%. In the following counties, where the ACS and/or IRS data appeared too noisy, we increased the interpolation weight above 75 percent: Lafayette (95%), Calhoun (89%), Dixie (88%), Baker (85%), Liberty (85%), DeSoto (84%), Gulf (80%), Franklin (79%), and Columbia (76%). We also made minor adjustments to the weights in Bradford, Gilchrist, Hardee, Hendry, Hernando, Hillsborough, Manatee, Miami-Dade, Sumter, and Washington counties. For the remaining 48 counties, we went with the weights produced by our custom method in Model 4.

After creating the PPH estimates for each county, we estimated the number of households by dividing the population in households by average household size. Estimates of the number of households for counties were added up to yield estimates of the number of households for the state. From these, we calculated average household size for Florida by dividing the population in households by the number of households.

Households

There were 8,529,067 households in Florida on April 1, 2020, an increase of 1,108,255 (14.9%) since April 1, 2010. At mid-decade, on April 1, 2015, we estimate that there were 7,752,507 households in Florida, an increase of 331,695 since April 1, 2010. The second half of the decade showed stronger growth, with an estimated increase of 776,560 households between April 1, 2015 and April 1, 2020. The growth patterns for households largely mirror those of Florida's total population, which also experienced stronger growth in the second half of the 2010s (BEBR Special Population Report #11).

The number of households was largest in Miami-Dade County each year between 2010–2020, followed by Broward, Palm Beach, Hillsborough, Orange, Pinellas, and Duval counties. Conversely, the following six counties had fewer than 5,000 households each year: Liberty, Lafayette, Union, Franklin, Glades, and Hamilton. In percentage terms, the largest increases between 2010–2020 occurred in Sumter (52.1%), Osceola (44.1%), St. Johns (38.9%), Walton (34.4%), Lake (29.4%), Nassau (24.7%), and Manatee (24.1%) counties. Glades (-6.2%), Calhoun (-5.5%), Hardee (-2.3%), Jackson (-1.9%), Madison (-1.5%), Liberty (-1.3%), Dixie (-1.1%), Holmes (-1.0%), Gadsden (-0.9%), and Bradford (-0.2%) counties all experienced a decline in households from 2010 to 2020.

Average Household Size

Florida's average household size declined substantially between 1950 and 1990, falling from 3.22 to 2.46. This decline was caused by falling birth rates, increasing divorce rates, a rising age at first marriage, and a substantial increase in Florida's older population. It remained constant between 1990 and 2000 before rising slightly to 2.48 in 2010 and declining again to 2.47 in 2020. This turnaround was caused by a leveling off of birth and divorce rates, and by shifts in Florida's demographic composition. Slightly more than half of Florida counties (39 out of 67) experienced a decrease in average household size between 2010–2020. These declines are associated with the aging of the population and are expected to continue for some time. Statewide, average household size increased modestly in the first half of the decade, peaking at 2.51 persons per household in 2015–2017, which was driven by increases in the largest counties; it declined after 2017 to reach 2.47 persons per household in 2020.

Average household size varies considerably among counties in Florida. In 2020, it was largest in Hendry (2.95), Osceola (2.95), Hardee (2.91), Baker (2.77), and Miami-Dade (2.75) counties, and smallest in Sumter (1.93), Pinellas (2.12), Charlotte (2.13), Sarasota (2.13), and Citrus (2.17) counties. While Sumter County's average household size of 1.93 in 2020 was the smallest in the decade, average household size peaked in 2011 and 2012 in Hardee County at 3.13 persons per household.

In general, average household size tends to be higher for Black than White households, for Hispanic than non-Hispanic households, and for households headed by young or middle-aged persons than for households headed by older persons. Although there is not a perfect correlation, the counties in Florida with the largest average household sizes tend to have low proportions of older residents and high proportions of Black or Hispanic residents, whereas counties with the smallest average household sizes tend to have high proportions of older residents and low proportions of Black and Hispanic residents.

**Differences in State Projections
2024 and 2023**

This page was intentionally left blank

Differences in State Projections: July 2024 and November 2023

The Bureau of Economic and Business Research (BEBR) at the University of Florida produces long-range projections of the Florida population that are consistent with the short-range projections produced by the Demographic Estimating Conference (DEC). This report summarizes the differences in methodology and outcomes between the projections produced in conjunction with the DEC held July 9, 2024 and the DEC held November 28, 2023.

The basic methodology used in producing these two sets of projections was the same: Both applied a cohort-component method in which births, deaths, and migration were projected separately, and both used a single year projection model. The main data sources were also the same. Differences between the projections made for the July 2024 DEC and the ones for the November 2023 DEC relate to updated data and weights on births, deaths, and migration.

The migration data used in both the July 2024 and the November 2023 BEBR projections came from Public Use Microdata Sample (PUMS) files based on American Community Survey (ACS) data. The November 2023 projections used data collected over the period 2011–2019, while the July 2024 projections used data collected over the period 2013–2022. In both projections, the later data years were weighted more strongly than the earlier years. PUMS data were used because they provide the only source of detailed information about domestic in- and out-migration, as well as migration from abroad. The migration rates were weighted differently in the two sets to approximate the projected migration components of their respective DEC. This resulted in overall higher migration projections in the later set through 2031, and slightly lower projections thereafter. Domestic migration followed a similar pattern,

with it being higher in the July 2024 projections until 2031 and slightly lower in the rest of the series. International migration was higher in the July 2024 projections until 2028, due to the components set forth by each DEC. From 2028–2050, however, the two projections were relatively similar; the July 2024 projection was an average of 573 persons higher each year compared to the November 2023 projection.

The survival rates for the November 2023 projections were based on Florida Life Tables for 2009–2011, while the survival rates for the July 2024 projections were based on Florida Life Tables for 2019. Each of these were adjusted based on changes in national survival rates as projected by the U.S. Census Bureau. We also made some changes to the projected number of deaths through 2028 to approximate the projected number of deaths as determined by the July 2024 DEC. Compared to the November 2023 projections, the July 2024 set projected fewer deaths from 2028–2050. The fertility rates in both sets were based on Florida birth data for 2009–2011. The number of recorded births in Florida has fluctuated over the years: they declined slightly from 2010–2012, went up from 2012–2016, declined again from 2016–2020, rebounded in 2020–2022, before declining again in 2022–2023, and finally increasing slightly in 2023–2024. We adjusted the number of births for 2020–2024 accordingly, with some small adjustments thereafter.

Both sets of BEBR projections incorporated the short-range projections agreed upon at the respective DECs. The July 2024 BEBR projections incorporated projections for 2024–2029 from the DEC held July 9, 2024, and the November 2023 BEBR projections incorporated projections for 2024–2028 from the DEC held November 28, 2023. Table 1 shows the projected state population from 2025 through 2050 for both sets of projections, including the numeric

and percent differences between the two sets. The July 2024 projections were higher than the November 2023 projections by about 40,000 (0.17%) in 2025, 73,000 (0.30%) in 2030, 100,000 (0.39%) in 2035, 107,000 (0.40%) in 2040, 83,000 (0.30%) in 2045, and 59,000 (0.21%) in 2050.

Table 1. BEBR State Projections: July 2024 and November 2023

Year	July 2024	Nov 2023	Difference	% Difference
2020	21,538,226	21,538,226	0	0
2025	23,332,606	23,292,200	40,406	0.17
2030	24,771,749	24,698,545	73,204	0.30
2035	25,914,575	25,814,954	99,621	0.39
2040	26,788,936	26,682,030	106,906	0.40
2045	27,492,380	27,409,376	83,004	0.30
2050	28,124,240	28,065,018	59,222	0.21

County	Place	No Change	Revised	2020 Census Count	Preliminary 2024 Estimate	Preliminary 2020–24 Change	Requested 2020–24 Change	Final 2020–24 Change	Final vs. Preliminary Estimate	Comments	
Baker	Glen St. Mary		1	463	472	9	38	28	19	EC data do not reflect new HUs supported by new water accounts between 4/1/2020 and 4/1/2024. We geocoded almost all of these, confirmed new construction over that period, and that there were no demolitions.	
Broward	Plantation		1	91,750	97,238	5,488	8,567	6,681	1,193	Revised estimate based on new certificates of occupancy and demolitions between 4/1/2020 and 4/1/2024. Resulting estimate is slightly lower than our BP-based estimate.	
Polk	Haines City		1	26,669	38,261	11,592	12,845	12,845	1,253	Challenged with certificates of occupancy and demolitions. Duke is missing their recent annexations. They used the correct occupancy and household size, so the change made was the same as the request. Revised estimate is lower than BP method estimate.	
Sarasota	North Port		1	74,793	91,964	17,171	18,596	17,606	435	Challenged with certificates of occupancy and demolitions over past year. Revised estimate is lower than BP-based estimate.	
Bay	Parker	1		4,010	4,427	417	836	417	0	Challenged late (9/20) using a projection from World Population Review.	
Bay	Springfield	1		8,075	9,010	935	1,372	935	0	They think FP&L misallocated their customers to Panama City, but they didn't know for how long (e.g., before 2020 Census). Didn't have time to properly research this and agreed with our estimate.	
Brevard	Melbourne	1		84,678	87,846	3,168	3,954	3,168	0	They projected 2024 population by extrapolating our 2020–23 estimated growth. Also provided certificates of occupancy and demolitions, which would have resulted in a slightly lower estimate than ours, so they agreed to our estimate.	
Clay	Keystone Heights	1		1,446	1,473	27	120	27	0	Used 2024 projection from World Population Review to challenge. After a discussion about this, they agreed to our estimate.	
Highlands	Avon Park	1		9,658	9,814	156	561	156	0	Challenged late (9/19) using Census Bureau's 2023 population estimate.	
Miami-Dade	Golden Beach	1		961	981	20	57	20	0	Challenged late (9/20) using certificates of occupancy, did not provide any demolitions, assumed 100% occupancy, and used incorrect PPH. Using the correct metrics, the certificates of occupancy-based estimate was identical to ours.	
Miami-Dade	North Bay Village	1		8,159	7,977	-182	-55	-182	0	Challenged with no information. Then challenged a second time, late (9/21), citing (1) a single development that was demolished and translated that to a loss of 55 and no city-wide data, and (2) our estimate from 2021.	
Monroe	Key West	1		26,444	26,327	-117	2,717	-117	0	Challenged on deadline (9/6) with no information. Then challenged late (9/20) with the number of sewer accounts x 2.2. We explained that sewer accounts were not the best source of residential units, we would need the change since 4/1/2020, and 2.2 is much too high (should be 1.78).	
Pasco	Unincorporated	1		513,983	579,775	65,792	n/a	65,792	0	Received late (9/13), and with no estimate or supporting information. No change was made.	
Pinellas	Clearwater	1		117,292	118,463	1,171	2,178	1,171	0	Challenged with data on annexations and new developments, did not provide demolitions, assumed 100% occupancy, and used wrong PPH. When we factored in demolitions and the correct occupancy and PPH, the certificates of occupancy-based estimate was slightly lower than ours, so they agreed to our estimate.	
Pinellas	Safety Harbor	1		17,072	16,762	-310	-13	-310	0	Challenged with annexations, a few building permits, but no city-wide data. After explaining our data and methods, they agreed with the estimate.	
Seminole	Winter Springs	1		38,342	39,131	789	996	789	0	Challenged using certificates of occupancy, but did not provide demolitions, assumed 100% occupancy, and used the wrong PPH. After explaining our data and methods, they agreed to the estimate.	
Sumter	Webster	1		778	948	170	542	170	0	Challenged using utility accounts (including non-residential ones) as of 8/28 (after 4/1, and no info on change since 2020), and assumed 100% occupancy and used the wrong PPH. After explaining our data and methods, they agreed to our estimate.

**Estimates Comparison
2020 to 2024**

This page was intentionally left blank

State Population Estimates Comparison, April 1, 2020 to April 1, 2024, BEBR vs. U.S. Census Bureau

The Bureau of Economic and Business Research (BEBR) at the University of Florida and the U.S. Census Bureau (USCB) produce population estimates for Florida each year. While the BEBR estimates are for April 1, the USCB estimates are for July 1. To make the analysis more meaningful, both estimates were compared for a common date, April 1 of each year. The USCB estimates for July 1 were converted to April 1 by taking three quarters of each annual population change and adding this change to the July 1 estimate of the previous year. For example, the April 1, 2024 estimate was created by taking three quarters of the July 1, 2023 to July 1, 2024 population change and adding it to the July 1, 2023 population estimate. While not a perfect comparison, it is preferable to comparing the original estimates that are three months apart.

Table 1 shows that the USCB population estimates that were released in December 2024 were lower than the BEBR population estimates in 2021 and 2022, but higher in 2023 and 2024. BEBR estimated Florida's population to grow by 360,758 persons between April 1, 2020 and April 1, 2021, which was 126,979 higher than the growth estimated by the USCB (233,779) in their latest Vintage 2024 set of estimates. In percentage terms, the estimated population of Florida according to BEBR was 0.59% higher on April 1, 2021 than the USCB estimate. From April 1, 2021 to April 1, 2022, BEBR estimated statewide population growth of 377,187, which was 93,313 lower than the growth estimated by the USCB (470,500). The percent difference between the BEBR and the USCB estimate for April 1, 2022 was 0.44%. The Census Bureau also estimated higher annual growth in 2022–23 and 2023–24 than BEBR (by 172,273 and 102,215, or 0.78% and 0.44%, respectively). By April 1, 2024, the Census Bureau's Vintage 2024 population estimates for Florida exceeded those made by BEBR by almost a quarter million persons (240,827).

What accounts for the differences between the BEBR and the USCB population estimates?

The BEBR population estimates for Florida use a bottom-up housing unit method approach, in which changes in population for counties and subcounty areas are based on changes in occupied housing units (or households). The first component of the housing unit method, the number of households, is estimated using three different data sources: residential building permits, residential electric customers, and, at the county level, homestead exemptions. The second component of the housing unit method, the average number of persons per household (PPH), is estimated based on local PPH values from the 2020 census, state-level changes in PPH since the 2020 census as measured by the American Community Survey, and local changes in the mix of single-family, multifamily, and mobile home units since the 2020 census. The BEBR population estimate for Florida equals the sum of all subcounty population estimates.

The USCB estimates, in contrast, are produced with an administrative record-based component of change method, which updates the 2020 census population using data on births, deaths, and domestic and international migration. Estimates for the nation are produced first, which are followed by county estimates that are controlled to the national estimates. Estimates for states are then created as the sum of each state's county estimates.

While different methodologies can lead to differences in the estimated population, for this year's estimates comparison, a change in the data used for the Census Bureau's estimates is more relevant. Occasionally, the Census Bureau makes changes to the methodology, or to the data sources that are used for estimating the population. The magnitude of the changes from vintage to vintage varies; it was quite small between Vintage 2022 and 2023 (fewer than 2,000 persons statewide for Florida), but larger between Vintage 2021 and 2022 (about 27,000). For

Vintage 2024, however, the Census Bureau implemented a major change to the net international migration component, which resulted in much higher net migration estimates. From 2021 to 2022, net international migration was estimated to be about 135,000 higher than in last year's estimates, and from 2022 to 2023, net migration was estimated to be about 164,000 higher than in Vintage 2023. These changes were due to the incorporation of administrative data on humanitarian migrant admissions from the U.S. Refugee Admissions Program and the Office of Homeland Security Statistics. The Census Bureau has offered little guidance on these changes so far, such as how the national level totals were distributed to states and counties. We expect to learn more about the changes at the upcoming meeting of the Federal-State Cooperative for Population Estimates.

We like to conclude by noting that although the BEBR estimates were compared to the USCB estimates in this report, the latter represent an alternative set of estimates, not a benchmark along the lines of the decennial census. There exists no "gold standard" against which both sets of estimates can currently be compared; we have to wait until the 2030 decennial census for such a comparison.

Table 1. State Comparison, BEBR vs. U.S. Census Bureau April 1, 2020 to April 1, 2024 Population Estimates

Notes:

U.S. Census Bureau estimates for July 1 were converted to April 1 by taking three quarters of the annual change and adding it to the July 1 estimate of the previous year. For example, the April 1, 2024 population estimate was created by taking three quarters of the July 1, 2023 to July 1, 2024 population change and adding it to the July 1, 2023 population estimate.

Methodology for Constructing Estimates of Total Population for Counties and Subcounty Areas in Florida

Richard Doty, Suzanne Roulston-Doty, and Stefan Rayer
Bureau of Economic and Business Research
University of Florida
January 2025

The Bureau of Economic and Business Research (BEBR) makes population estimates for every county and subcounty area in Florida, with subcounty areas defined as incorporated cities, towns, and villages, and the unincorporated balance of each county. County estimates are calculated as the sum of the subcounty estimates for each county, and the state estimate is calculated as the sum of the county estimates. The estimates refer solely to permanent residents of Florida; they do not include seasonal or other types of temporary residents.

The estimates are produced using the housing unit method, in which changes in population are based on changes in occupied housing units (or households). This is the most commonly used method for making local population estimates in the United States because it can utilize a wide variety of data sources, can be applied at any level of geography, and can produce estimates that are at least as accurate as those produced by any other method.

The foundation of the housing unit method is the fact that almost everyone lives in some type of housing structure, whether a traditional single-family unit, an apartment, a mobile home, a college dormitory, or a state prison. The population of any geographic area can be calculated as the number of occupied housing units (households) times the average number of persons per household (PPH), plus the number of persons living in group quarters such as college dormitories, military barracks, nursing homes, and prisons:

$$P_t = (H_t \times PPH_t) + GQ_t$$

where P_t is the population at time t , H_t is the number of occupied housing units at time t , PPH_t is the average number of persons per household at time t , and GQ_t is the group quarters population at time t . Estimates of the number of people without permanent living quarters (e.g., the homeless population) are included in estimates of the group quarters population.

This is an identity, not an estimate. If these three components were known exactly, the total population would also be known. The problem, of course, is that these components are almost never known exactly. Rather, they must be estimated from various data sources, using one or more of several possible techniques. In this report, we describe the data and techniques that we will use this year to develop population estimates for Florida's counties and subcounty areas for April 1, 2025.

Households

Census definitions require a person to be counted as an inhabitant of his/her usual place of residence, which is generally construed to mean the place where she/he lives and sleeps most of the time. This place is not necessarily the same as one's legal or voting residence. A household is the person or group of people occupying a housing unit; by definition, the number of occupied housing units is the same as the number of households. Households refer solely to usual residents, and a housing unit is classified as vacant even when it is continuously occupied, if all the occupants are temporary residents staying only for a few days, weeks, or months.

BEER uses three different data sources to estimate the number of households in Florida. Our primary data source is active residential electric customers. We collect these data from each of the state's 53 electric utility companies. Households can be estimated by constructing a ratio of households to active residential electric customers using data from the most recent census year (e.g., 2020) and multiplying that ratio times the number of active residential customers in some later year (e.g., 2025). This procedure assumes that no changes have occurred in electric company bookkeeping practices, in the vacancy rate of active residential electric customers, or in the proportion of those customers who are permanent residents. Although changes do occur, they are generally fairly small. In some places we adjust the household/electric customer ratio to account for changes in the vacancy rate or the proportion of housing units occupied by permanent residents.

We sometimes filter electric customer data to exclude minimum use customers. Minimum use customers are those using less than 200 kilowatt (kWh) hours per month. We believe these customers typically represent seasonal or other part-time residents or vacant units and excluding them may give a more accurate measure of permanent residents. Because we estimate the change in population since the 2020 Census, excluding minimum use customers can capture changes in unit occupancy over that period. These data are not available for all areas of the state, but in places in which the data are available and appear to be reliable, we often use them in conjunction with other data sources.

Our second data source is residential building permits, as collected and distributed by the U.S. Department of Commerce. The housing inventory in 2025 for a city or county that issues building permits can be estimated by adding permits issued since 2020 to the units counted in the 2020 census, subtracting units lost to destruction, demolition, or conversion to other uses, and adding (or subtracting) any units gained (or lost) due to annexations. The time lag between the issuance of a permit and the completion of a unit is assumed to be three months for single-family units and fifteen months for multifamily units. Building permits are not issued for mobile homes, but proxies can be derived from records of shipments to mobile home dealers in Florida. Creating a housing inventory for an entire county requires complete permit data for every permitting agency within the county. Although such data are not always available, coverage is sufficient in most Florida cities and counties to provide useful information.

There are no readily available data sources providing comprehensive up-to-date information on occupancy rates that are as reliable as those produced by the latest decennial census. Accurate information can be obtained through special censuses or large sample surveys, but in most instances these methods are too expensive to be feasible. A common solution is to use the occupancy rates reported in the most recent decennial census. We base our occupancy estimates on these values, but we may make adjustments to account for factors reflecting changes in occupancy rates over time. For the 2025 estimates, we will use occupancy rates from Census 2020. In some cases, slight changes in occupancy since 2020 may be estimated in places where we use electrical customer data and can exclude minimum use customers. We may also use data from the U.S. Census Bureau's American Community Survey (ACS) in cases where it shows statistically significant trends over time since the 2020 census.

The product of the inventory figure and the occupancy rate provides an estimate of the number of households. There are several potential problems with this estimate. Time lags between the issuance of permits and the completion of units may vary from place to place and from year to year. The proportion of permits resulting in completed units is usually unknown. Data on demolitions and conversions are incomplete and data on mobile homes must be estimated indirectly. Reliable estimates of changes in occupancy rates are generally unavailable. Certificate-of-occupancy data, where available, can eliminate problems related to completion rates and time lags, but not those related to occupancy rates, demolitions, and conversions. Although these problems limit the usefulness of the data in some places, building permit data often provide reasonably accurate estimates of households.

Our third data source for estimates is the number of homestead exemptions by county reported by the Florida Department of Revenue. Households can be estimated by constructing a ratio of households to exemptions using data from the most recent census year (e.g., 2020) and multiplying that ratio times the number of exemptions in some later year (e.g., 2025). An important advantage of these data is that they cover only housing units occupied by permanent residents, thereby excluding the impact of seasonal and other non-permanent residents. The primary disadvantage is that the data do not include households occupied by renters or other non-homeowners, but those households often change at a similar rate to the households with homestead exemptions. Homestead exemption data is also available from each county's property appraiser at the property parcel level, which can be summarized by subcounty area. We occasionally use these data to inform our decision making in places where our other primary data sources show significantly different results.

Electric customer, building permit, and homestead exemption data all provide useful information regarding changes in households. Previous research on BEBR population estimates has shown that household estimates based on electric customer data are—on average—more accurate than those based on building permit and other data. However, we use our professional judgment to decide which data source(s) to use in each specific county and subcounty area. In many instances, we use averages of estimates from more than one data source. We also sometimes use GIS-based property parcel data (along with year-built information and detailed land use codes from the

Florida Department of Revenue) or manual counts from aerial imagery to evaluate which data source is best for a particular place.

Persons per Household

The second component of the housing unit method is the average number of persons per household (PPH). Florida's PPH dropped steadily from 3.22 in 1950 to 2.46 in 1990 but then leveled off, remaining constant between 1990 and 2000. It rose to 2.48 in 2010 and slightly dropped to 2.47 in 2020. There is a substantial amount of variation among local areas in Florida, with values in 2020 ranging from 1.9 to 3.0 for counties and from less than 1.4 to more than 3.8 for subcounty areas. PPH values have risen over time in some cities and counties and declined in others.

We note that the U.S. Census Bureau released PPH data for Census 2020 in the Supplemental Demographic and Housing Characteristics File (S-DHC) in September 2024, but the data are only available at the national and state levels due to data privacy concerns. Consequently, like last year, we will base our PPH estimates for each county and subcounty area on the local PPH value that we calculated from other Census 2020 data by dividing the population not in group quarters by the number of occupied housing units. In some instances, we may estimate changes in PPH since 2020 using statistically significant trends in data from the American Community Survey or changes in the mix of single-family, multifamily, and mobile home units. We will use our professional judgment to decide which data sources and techniques to use in each county and subcounty area. We will ensure that the population-weighted state average of our calculated values for each county and subcounty area is consistent with the state-level PPH estimate from the Census 2020 S-DHC file.

Group Quarters Population

The household population is calculated as the product of households and PPH. To obtain an estimate of the total population, we must add an estimate of the group quarters population. In most places, we estimate the group quarters population by assuming that it accounts for the same proportion of total population in 2025 as it did in 2020. For example, if the group quarters population accounted for 2% of the total population in 2020, we assume that it will account for 2% in 2025. In places where there are large group quarters facilities, we collect data directly from the administrators of those facilities and add those estimates to the other group quarters population. Inmates in state and federal institutions are accounted for separately in all local areas; these data are available from the Federal Bureau of Prisons, the Florida Department of Corrections, the Florida Department of Veteran Affairs, the Florida Agency for Persons with Disabilities, the Florida Department of Health, the Florida Department of Juvenile Justice, and the Florida Department of Children and Families. The total population estimate is made by adding the estimate of the group quarters population to the estimate of the household population.

Conclusion

The population estimates produced by BEBR are calculated by multiplying the number of households by the average number of persons per household and adding the number of persons living in group quarters. This methodology is conceptually simple but effective. It utilizes data that are available for all local areas, its components respond rapidly to population movements, and it can be applied systematically and uniformly everywhere in the state. A comparison of population estimates with census results for 1980, 1990, 2000, 2010, and 2020 showed the BEBR estimates to be quite accurate, especially when compared to other sets of estimates. We believe the housing unit method is the most effective method for making city and county population estimates in Florida and that it produces reliable estimates that provide a solid foundation for budgeting, planning, and analysis.

- 1 BEBR estimate April 1st (2000, 2010, and 2020 are Census counts; 2001–2019 are revised intercensal estimates)
- 2 Census estimate July 1st (2000, 2010, and 2020 are July 1st estimates, not April 1st decennial census counts; 2000–2009 are revised intercensal estimates)
- 3 Active residential electric customers March 31st
- 4 Florida Property Valuations and Tax Data Book (DOR) - January 1st of each year
- 5 Florida Agency for Workforce Innovation - Labor Market Statistics - Local Area Unemployment Statistics - March (seasonally adjusted)
- 6a Florida Department of Education - Fall school enrollment (Public Schools)
- 6b Florida Department of Education - Fall school enrollment (Private Schools)
- 7 US Department of Commerce - Permits issued prior calendar year for single-family units, two years prior for multifamily units, no lag for mobile home units and demolitions
- 8 Census estimate July 1st (2000, 2010, and 2020 are July 1st estimates, not April 1st decennial census counts; 2000–2009 are revised intercensal estimates)

Notes:**All Companies (March):**

The March total has been adjusted downward by 0.373% each year prior to 2020 to make the series comparable to the new Duke data used for the estimates. The totals for 2020 and 2021 are based on the new Duke data and are about 36,000–37,000 lower than the EC reports for those years.

Florida Power & Light:

Data for FP&L raised by 1% prior to July 2013, reduced gradually through December 2013. Includes City of Vero Beach adjustment, which transferred to FP&L in December 2018 to January 2019.

Duke:

Includes Hardee County adjustment (transfer from Duke to Peace River Electric Coop) through July 2019. Duke changed their billing system in November 2021. Data for earlier months were inflated due to inclusion of some non-housing units. We lowered the data prior to November 2021 by 13,680 each month to make the series comparable with the new and improved billing system. Also included are updated monthly customer counts since November 2021.

Tampa Electric:

Adjusted data for TECO for January 2017 through April 2018.
